Job Market Paper

Firm Debt Relief in Financial Downturn

Abstract: I study the stabilization effects of firm-specific debt relief in a DSGE model calibrated to U.S. data, including the skewed size distribution of firms. Firms face persistent idiosyncratic risk and financial frictions that give rise to an endogenous distribution over capital, debt, productivity, and age, while leading to capital misallocation and life-cycle effects. I model financial frictions by assuming collateralized borrowing. A shock to firms' access to credit exacerbates present misallocation, leading to a crisis similar to the Great Recession. This creates a role for policy: government borrows on behalf of financially constrained firms and provides debt relief, allowing firms to invest more. Policy that targets firms with the highest levels of excess return to investment improves aggregates the most, reducing the drop in output from 2.25 percent below steady state to 1 percent, a reduction of over 50 percent at the no-policy trough date. Understanding that this is not a readily observable policy target, I consider firm size and age as alternative targets. The model is well-suited for this, as it produces an age-size distribution matching U.S. data. Contrary to motivation for policy aimed at small firms, I find that policy that targets medium size firms outperforms these other targets in dampening a recession, though they all fall short of the excess return policy. However, as the government borrows to pay for policy, the eventual increase in taxes to pay the debt slows the final stages of the recovery.
